# Online Supplement to 

# "Optimal Model Averaging Estimation for Partially Linear Models" 

Xinyu Zhang<br>Chinese Academy of Sciences, and Capital University of Economics and Business Wendun Wang<br>Econometric Institute, Erasmus University Rotterdam, and Tinbergen Institute

This online supplement contains two parts: the first part is Appendices which provide the proofs of Theorems 1 and 2; and the second part consists of four sections with additional theoretical and simulation results. Section S. 1 provides further explanations on the conditions for the theorems. Section S. 2 provides the detailed proof of Theorem 1. Section S. 3 presents additional simulation studies, including the comparison with linear model averaging, data generation process with a diverging number of candidate models, and the case with autoregressive errors. Section S. 4 presents additional figures and tables for the empirical application.

## Part 1: Appendices

## A. 1 Proof of Theorem 1

For convenience purposes, similar to the proof in Zhang et al. (2013), we treat $\mathbf{X}$ and $\mathbf{Z}$ as non-random throughout the Appendix. Allowing for randomness would not invalidate the proof, because all our technical conditions hold almost surely.

Denote the largest singular value of a matrix $\mathbf{A}$ by $\lambda_{\max }(\mathbf{A})$. From the first part of Condition 2, we have

$$
\begin{equation*}
\lambda_{\max }(\boldsymbol{\Omega})=O(1) . \tag{A.1}
\end{equation*}
$$

The proof of (2.6) is similar to that of Theorem 1' in Wan et al. (2010). Following their steps and using (A.1), transformation $\boldsymbol{\epsilon}^{*}=\boldsymbol{\Omega}^{-1 / 2} \boldsymbol{\epsilon}$, and Condition 2, the only argument that we need to verify to complete the proof is that

$$
\begin{equation*}
\max _{s}\left\{\lambda_{\max }\left(\mathbf{P}_{s}\right)\right\}=O(1) \quad \text { and } \quad \max _{s}\left\{\lambda_{\max }\left(\mathbf{P}_{(s)} \mathbf{P}_{(s)}^{\mathrm{T}}\right)\right\}=O(1) \tag{A.2}
\end{equation*}
$$

Therefore, in this Appendix, we only focus on the proof of (A.2), but we provide a detailed proof of Theorem 1 in Section S. 2 of this supplement.

By an inequality of Reisz (see Hardy et al. (1952) or Speckman (1988)), we know that

$$
\begin{equation*}
\lambda_{\max }^{2}\left(\mathbf{K}_{(s)}\right) \leq \max _{i} \sum_{j=1}^{n}\left|K_{(s), i j}\right| \max _{j} \sum_{i=1}^{n}\left|K_{(s), i j}\right| . \tag{A.3}
\end{equation*}
$$

In addition, it is well known that for any two $n \times n$ matrices $\mathbf{B}_{1}$ and $\mathbf{B}_{2}$ (see, for example, Li (1987))

$$
\begin{equation*}
\lambda_{\max }\left(\mathbf{B}_{1} \mathbf{B}_{2}\right) \leq \lambda_{\max }\left(\mathbf{B}_{1}\right) \lambda_{\max }\left(\mathbf{B}_{2}\right) \text { and } \lambda_{\max }\left(\mathbf{B}_{1}+\mathbf{B}_{2}\right) \leq \lambda_{\max }\left(\mathbf{B}_{1}\right)+\lambda_{\max }\left(\mathbf{B}_{2}\right) . \tag{A.4}
\end{equation*}
$$

From (A.4) and $\lambda_{\max }\left(\widetilde{\mathbf{P}}_{(s)}\right)=1$, we obtain that for $1 \leq s \leq S_{n}$

$$
\begin{align*}
\lambda_{\max }\left(\mathbf{P}_{(s)} \mathbf{P}_{(s)}^{\mathrm{T}}\right) & \leq \lambda_{\max }^{2}\left(\mathbf{P}_{(s)}\right) \\
& =\lambda_{\max }^{2}\left\{\widetilde{\mathbf{P}}_{(s)}\left(\mathbf{I}_{n}-\mathbf{K}_{(s)}\right)+\mathbf{K}_{(s)}\right\} \\
& \leq\left[\lambda_{\max }\left(\widetilde{\mathbf{P}}_{(s)}\right)\left\{1+\lambda_{\max }\left(\mathbf{K}_{(s)}\right)\right\}+\lambda_{\max }\left(\mathbf{K}_{(s)}\right)\right]^{2} \\
& =\left[\left\{1+\lambda_{\max }\left(\mathbf{K}_{(s)}\right)\right\}+\lambda_{\max }\left(\mathbf{K}_{(s)}\right)\right]^{2}, \tag{A.5}
\end{align*}
$$

which, together with (A.3) and Condition 1, implies (A.2). This completes the proof.

## A. 2 Proof of Theorem 2

Note that

$$
\widehat{C}_{n}(\mathbf{w})=C_{n}(\mathbf{w})+\operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \widehat{\boldsymbol{\Omega}}_{\left(s^{*}\right)}\right\}-\operatorname{trace}\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega}\} .
$$

Hence, from the proof of Theorem 1, in order to prove (2.6), we only need to verify that

$$
\begin{equation*}
\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \widehat{\boldsymbol{\Omega}}_{\left(s^{*}\right)}\right\}-\operatorname{trace}\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega}\}\right| / R_{n}(\mathbf{w})\right]=o_{p}(1) . \tag{A.6}
\end{equation*}
$$

Let $\mathbf{Q}_{(s)}=\operatorname{diag}\left(\rho_{11}^{(s)}, \ldots, \rho_{n n}^{(s)}\right)$ and $\mathbf{Q}(\mathbf{w})=\sum_{s=1}^{S_{n}} w_{s} \mathbf{Q}_{(s)}$. Then, from (2.7), we have

$$
\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \widehat{\boldsymbol{\Omega}}_{\left(s^{*}\right)}\right\}-\operatorname{trace}\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega}\}\right| / R_{n}(\mathbf{w})\right]
$$

$$
\begin{align*}
= & \sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\left(\mathbf{y}-\mathbf{P}_{\left(s^{*}\right)} \mathbf{y}\right)^{\mathrm{T}} \mathbf{Q}(\mathbf{w})\left(\mathbf{y}-\mathbf{P}_{\left(s^{*}\right)} \mathbf{y}\right)-\operatorname{trace}\{\mathbf{Q}(\mathbf{w}) \boldsymbol{\Omega}\}\right| / R_{n}(\mathbf{w})\right] \\
= & \sup _{\mathbf{w} \in \mathcal{W}}\left[\mid\left(\boldsymbol{\epsilon}+\boldsymbol{\mu}-\mathbf{P}_{\left(s^{*}\right)} \boldsymbol{\mu}-\mathbf{P}_{\left(s^{*}\right)} \boldsymbol{\epsilon}\right)^{\mathrm{T}} \mathbf{Q}(\mathbf{w})\left(\boldsymbol{\epsilon}+\boldsymbol{\mu}-\mathbf{P}_{\left(s^{*}\right)} \boldsymbol{\mu}-\mathbf{P}_{\left(s^{*}\right)} \boldsymbol{\epsilon}\right)\right. \\
& \left.-\operatorname{trace}\{\mathbf{Q}(\mathbf{w}) \boldsymbol{\Omega}\} \mid / R_{n}(\mathbf{w})\right] \\
\leq & \sup _{\mathbf{w} \in \mathcal{W}}\left[\mid \boldsymbol{\epsilon}^{\mathrm{T}}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}(\mathbf{w})\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\epsilon}\right. \\
& \left.-\operatorname{trace}\left\{\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}(\mathbf{w})\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\Omega}\right\} \mid / R_{n}(\mathbf{w})\right] \\
& +2 \sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\boldsymbol{\epsilon}^{\mathrm{T}}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}(\mathbf{w})\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\mu}\right| / R_{n}(\mathbf{w})\right] \\
& +\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\boldsymbol{\mu}^{\mathrm{T}}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}(\mathbf{w})\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\mu}\right| / R_{n}(\mathbf{w})\right] \\
& +\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\operatorname{trace}\left(\mathbf{P}_{\left(s^{*}\right)}^{\mathrm{T}} \mathbf{Q}(\mathbf{w}) \mathbf{P}_{\left(s^{*}\right)} \boldsymbol{\Omega}\right)\right| / R_{n}(\mathbf{w})\right] \\
& +2 \sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\operatorname{trace}\left(\mathbf{P}_{\left(s^{*}\right)}^{\mathrm{T}} \mathbf{Q}(\mathbf{w}) \boldsymbol{\Omega}\right)\right| / R_{n}(\mathbf{w})\right] \\
\equiv & \Xi_{1}+\Xi_{2}+\Xi_{3}+\Xi_{4}+\Xi_{5} . \tag{A.7}
\end{align*}
$$

Define $\rho=\max _{s} \max _{i}\left|\rho_{i i}^{(s)}\right|$. From (A.3), (A.4), and Conditions 4-5, we have

$$
\begin{align*}
\rho \leq & c n^{-1} \max _{s}\left\{\left|\operatorname{trace}\left(\mathbf{P}_{(s)}\right)\right|\right\} \\
\leq & c n^{-1} \max _{s}\left\{\left|\operatorname{trace}\left(\widetilde{\mathbf{P}}_{(s)}\right)-\operatorname{trace}\left(\widetilde{\mathbf{P}}_{(s)} \mathbf{K}_{(s)}\right)\right|\right\}+c n^{-1} \max _{s}\left|\operatorname{trace}\left(\mathbf{K}_{(s)}\right)\right| \\
\leq & c n^{-1} \max _{s}\left|\operatorname{trace}\left(\widetilde{\mathbf{P}}_{(s)}\right)\right|+c n^{-1} \max _{s}\left|\operatorname{trace}\left(\widetilde{\mathbf{P}}_{(s)} \mathbf{K}_{(s)}\right)\right|+c n^{-1} \max _{s}\left|\operatorname{trace}\left(\mathbf{K}_{(s)}\right)\right| \\
= & c n^{-1} \widetilde{p}+c n^{-1} 2^{-1} \max _{s}\left|\operatorname{trace}\left(\widetilde{\mathbf{P}}_{(s)} \mathbf{K}_{(s)}+\mathbf{K}_{(s)}^{\mathrm{T}} \widetilde{\mathbf{P}}_{(s)}\right)\right|+c n^{-1} \max _{s}\left|\operatorname{trace}\left(\mathbf{K}_{(s)}\right)\right| \\
\leq & c n^{-1} \widetilde{p}+c n^{-1} 2^{-1} \max _{s}\left\{\lambda_{\max }\left(\widetilde{\mathbf{P}}_{(s)} \mathbf{K}_{(s)}+\mathbf{K}_{(s)}^{\mathrm{T}} \widetilde{\mathbf{P}}_{(s)}\right) \operatorname{rank}\left(\widetilde{\mathbf{P}}_{(s)} \mathbf{K}_{(s)}+\mathbf{K}_{(s)}^{\mathrm{T}} \widetilde{\mathbf{P}}_{(s)}\right)\right\} \\
& \quad+c n^{-1} \max _{s}\left|\operatorname{trace}\left(\mathbf{K}_{(s)}\right)\right| \\
\leq & c n^{-1} \widetilde{p}+c n^{-1} 2 \max _{s}\left\{p_{s} \lambda_{\max }\left(\widetilde{\mathbf{P}}_{(s)}\right) \lambda_{\max }\left(\mathbf{K}_{(s)}\right)\right\}+c n^{-1} \max _{s}\left|\operatorname{trace}\left(\mathbf{K}_{(s)}\right)\right| \\
= & O\left(n^{-1} \widetilde{p}+n^{-1} h^{-1}\right) . \tag{A.8}
\end{align*}
$$

It follows from (2.3) and Condition 2 that

$$
\begin{equation*}
\xi_{n} \rightarrow \infty, S_{n} \xi_{n}^{-2 G}=o(1), \quad \text { and } \quad \xi_{n}^{-2}\left\|\mathbf{P}_{\left(s^{*}\right)} \boldsymbol{\mu}-\boldsymbol{\mu}\right\|^{2}=o(1) \tag{A.9}
\end{equation*}
$$

Using (A.1), (A.2), (A.8), Chebyshev's inequality, and Theorem 2 of Whittle (1960), we can obtain that, for any $\delta>0$,

$$
\begin{aligned}
\operatorname{Pr}\left(\Xi_{1}>\delta\right) \leq & \sum_{s=1}^{S_{n}} \operatorname{Pr}\left[\mid \boldsymbol{\epsilon}^{\mathrm{T}}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}_{(s)}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\epsilon}\right. \\
& \left.\quad \operatorname{trace}\left\{\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}_{(s)}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\Omega}\right\} \mid>\delta \xi_{n}\right]
\end{aligned}
$$

$$
\begin{align*}
\leq & \delta^{-2 G} \xi_{n}^{-2 G} \sum_{s=1}^{S_{n}} E\left[\epsilon^{\mathrm{T}}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}_{(s)}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\epsilon}\right. \\
\quad & \left.\quad \operatorname{trace}\left\{\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}_{(s)}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\Omega}\right\}\right]^{2 G} \\
\leq & c_{1} \delta^{-2 G} \xi_{n}^{-2 G} \sum_{s=1}^{S_{n}} \operatorname{trace}^{G}\left\{\boldsymbol{\Omega}^{1 / 2}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}_{(s)}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\Omega}\right. \\
& \left.\times\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right)^{\mathrm{T}} \mathbf{Q}_{(s)}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\Omega}^{1 / 2}\right\} \\
\leq & c_{1} \delta^{-2 G} \xi_{n}^{-2 G} \lambda_{\max }^{4 G}\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \lambda_{\max }^{2 G}(\boldsymbol{\Omega}) n^{G} \rho^{2 G} S_{n} \\
= & \xi_{n}^{-2 G} S_{n}\left\{O\left(n^{-1} \widetilde{p}^{2}+n^{-1} h^{-2}\right)\right\}^{G}, \tag{A.10}
\end{align*}
$$

where $c_{1}$ is a positive constant and $G$ is the integer defined in Condition 2. It follows from (A.9)-(A.10) and Condition 6 that $\Xi_{1}=o_{p}(1)$.

Using (A.1), (A.2), (A.4), (A.8) and (A.9), we have

$$
\begin{align*}
\Xi_{2} & \leq 2 \xi_{n}^{-1}\left\|\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\mu}\right\| \sup _{\mathbf{w} \in \mathcal{W}}\left\|\mathbf{Q}(\mathbf{w})\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\epsilon}\right\| \\
& \leq 2 \xi_{n}^{-1}\left\|\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\mu}\right\| \sup _{\mathbf{w} \in \mathcal{W}}\left\{\rho\left\|\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\epsilon}\right\|\right. \\
& \leq 2 \xi_{n}^{-1}\left\|\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\mu}\right\| \rho\left\{1+\lambda_{\max }\left(\mathbf{P}_{\left(s^{*}\right)}\right)\right\}\|\boldsymbol{\epsilon}\| \\
& =o(1) O_{p}\left(n^{-1 / 2} \widetilde{p}+n^{-1 / 2} h^{-1}\right) \tag{A.11}
\end{align*}
$$

which, along with Condition 6 , implies that $\Xi_{2}=o_{p}(1)$.
Using (A.2), (A.4), (A.8), (A.9) and Condition 3, we have

$$
\begin{align*}
\Xi_{3} & \leq \xi_{n}^{-1} \rho\left\|\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\mu}\right\|^{2} \\
& \leq \xi_{n}^{-1}\left\|\left(\mathbf{I}_{n}-\mathbf{P}_{\left(s^{*}\right)}\right) \boldsymbol{\mu}\right\| \rho\|\boldsymbol{\mu}\|\left\{1+\lambda_{\max }\left(\mathbf{P}_{\left(s^{*}\right)}\right)\right\} \\
& =o(1) O\left(n^{-1 / 2} \widetilde{p}+n^{-1 / 2} h^{-1}\right) \tag{A.12}
\end{align*}
$$

which, along with Condition 6 , implies that $\Xi_{3}=o(1)$.
Using (A.1), (A.2) and (A.4), we have

$$
\begin{align*}
\Xi_{4}+\Xi_{5} \leq & 2 \xi_{n}^{-1} \operatorname{rank}\left(\mathbf{P}_{\left(s^{*}\right)}\right) \sup _{\mathbf{w} \in \mathcal{W}}\left[\lambda_{\max }\left\{\mathbf{P}_{\left(s^{*}\right)}^{\mathrm{T}} \mathbf{Q}(\mathbf{w}) \mathbf{P}_{\left(s^{*}\right)} \boldsymbol{\Omega}\right\}\right] \\
& +4 \xi_{n}^{-1} \operatorname{rank}\left(\mathbf{P}_{\left(s^{*}\right)}\right) \sup _{\mathbf{w} \in \mathcal{W}}\left[\lambda_{\max }\left\{\mathbf{P}_{\left(s^{*}\right)}^{\mathrm{T}} \mathbf{Q}(\mathbf{w}) \boldsymbol{\Omega}\right\}\right] \\
\leq & 2 \xi_{n}^{-1} \widetilde{p} \rho \lambda_{\max }^{2}\left(\mathbf{P}_{\left(s^{*}\right)}\right) \lambda_{\max }(\boldsymbol{\Omega})+4 \xi_{n}^{-1} \widetilde{p} \rho \lambda_{\max }\left(\mathbf{P}_{\left(s^{*}\right)}\right) \lambda_{\max }(\boldsymbol{\Omega}) \\
= & \xi_{n}^{-1} O\left(n^{-1} \widetilde{p}^{2}+n^{-1} h^{-1} \widetilde{p}\right), \tag{A.13}
\end{align*}
$$

which, along with (A.9) and Condition 6 , implies that $\Xi_{4}+\Xi_{5}=o(1)$. Therefore, we can get (A.6). This completes the proof.

## Part 2: Additional theoretical and simulation results

## S. 1 Further discussions on conditions

Following Appendix A of Speckman (1988), we first provide justifications of Conditions 4 and 1. We consider a simple case with $\mathbf{Z}_{(s), i}$ being a scalar $Z_{(s), i}$. Then, $K_{(s), i i}=$ $k_{h_{s}}(0) / \sum_{j^{*}=1}^{n} k_{h_{s}}\left(Z_{(s), i}-Z_{(s), j^{*}}\right)$, by which, we obtain

$$
\begin{equation*}
K_{(s), i i}=O\left(n^{-1} h_{s}^{-1}\right), \tag{S.1}
\end{equation*}
$$

following the assumption (g) of Speckman (1988), which we quote below
"There is a probability density $p(z)$ of $Z_{(s), i}$ on [0,1] such that $n^{-1} \sum_{i=1}^{n} c\left(Z_{(s), i}\right) \rightarrow \int_{0}^{1} c(z) p(z) d z$ as $n \rightarrow \infty$ for any continuous function $c(z)$."

Condition 4 directly follows from (S.1). If $K_{(s), i j}$ is non-negative, then the row sums of $\mathbf{K}_{(s)}$ are identically unity. Hence, the first bound of Condition 1 is trivial. Assumption (g) of Speckman (1988) implies that the column sums can be approximated by integrals and the dependence on $h_{s}$ can be regarded to vanish as $n \rightarrow \infty$. Therefore, the second bound of Condition 1 is also reasonable.

Now we examine Condition 2. The first part of Condition 2 is a moment condition. To explain the second part of Condition 2, we define $\varrho_{n}=\max _{1 \leq s \leq S} R_{n}\left(\mathbf{w}_{s}^{o}\right)$. The second part of Condition 2 is implied by $S_{n}^{2} \xi_{n}^{-2 G} \varrho_{n}^{G} \rightarrow 0$, and it depends on the infimum risk of model averaging estimators (i.e., $\xi_{n}$ ) and the maximum risk of model selection estimators (i.e., $\left.\varrho_{n}\right)$. Both $\xi_{n}$ and $\varrho_{n}$ depend on the magnitude of model misspecification, which is difficult to quantify in practice.

Finally, we discuss Condition 5. As explained in Hansen \& Racine (2012), this assumption excludes only extremely unbalanced designs, for example, where a single observation remains relevant asymptotically. Therefore, Condition 5 is also a reasonable assumption.

## S. 2 Detailed proof of Theorem 1

Let $\mathbf{A}(\mathbf{w})=\mathbf{I}_{n}-\mathbf{P}(\mathbf{w})$. Note that

$$
C_{n}(\mathbf{w})=L_{n}(\mathbf{w})+\|\boldsymbol{\epsilon}\|^{2}+2 \boldsymbol{\epsilon}^{\mathrm{T}} \mathbf{A}(\mathbf{w}) \boldsymbol{\mu}+2\left[\operatorname{trace}\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega}\}-\boldsymbol{\epsilon}^{\mathrm{T}} \mathbf{P}(\mathbf{w}) \boldsymbol{\epsilon}\right] .
$$

Similar to the proof of Theorem 2.1 of Li (1987), Theorem 1 is valid if the following equations hold:

$$
\begin{gather*}
\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\boldsymbol{\epsilon}^{\mathrm{T}} \mathbf{A}(\mathbf{w}) \boldsymbol{\mu}\right| / R_{n}(\mathbf{w})\right]=o_{p}(1),  \tag{S.2}\\
\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\operatorname{trace}\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega}\}-\boldsymbol{\epsilon}^{\mathrm{T}} \mathbf{P}(\mathbf{w}) \boldsymbol{\epsilon}\right| / R_{n}(\mathbf{w})\right]=o_{p}(1), \tag{S.3}
\end{gather*}
$$

and

$$
\begin{equation*}
\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|L_{n}(\mathbf{w})\right| / R_{n}(\mathbf{w})-1 \mid\right]=o_{p}(1) \tag{S.4}
\end{equation*}
$$

Therefore, the main task of the proof is to verify (S.2)-(S.4).
First, from (2.3) and Condition 2, we can obtain (S.2) using exactly the same proving steps as those in (A.1) of Wan et al. (2010). Second, to verify (S.3), we let $\boldsymbol{\epsilon}^{*}=\boldsymbol{\Omega}^{-1 / 2} \boldsymbol{\epsilon}$. From (2.3), (A.1) and Theorem 2 of Whittle (1960), we have that for any $\delta>0$,

$$
\begin{align*}
& \operatorname{Pr}\left\{\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\operatorname{trace}\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega}\}-\boldsymbol{\epsilon}^{\mathrm{T}} \mathbf{P}(\mathbf{w}) \boldsymbol{\epsilon}\right| / R_{n}(\mathbf{w})\right]>\delta\right\} \\
= & \operatorname{Pr}\left\{\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\operatorname{trace}\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega}\}-\boldsymbol{\epsilon}^{* \mathrm{~T}} \boldsymbol{\Omega}^{1 / 2} \mathbf{P}(\mathbf{w}) \boldsymbol{\Omega}^{1 / 2} \boldsymbol{\epsilon}^{*}\right| / R_{n}(\mathbf{w})\right]>\delta\right\} \\
\leq & \sum_{s=1}^{S_{n}} \operatorname{Pr}\left\{\left|\operatorname{trace}\left\{\mathbf{P}\left(\mathbf{w}_{s}^{o}\right) \boldsymbol{\Omega}\right\}-\boldsymbol{\epsilon}^{* \mathrm{~T}} \boldsymbol{\Omega}^{1 / 2} \mathbf{P}\left(\mathbf{w}_{s}^{o}\right) \boldsymbol{\Omega}^{1 / 2} \boldsymbol{\epsilon}^{*}\right|>\delta \xi_{n}\right\} \\
\leq & \sum_{s=1}^{S_{n}} E\left\{\left[\operatorname{trace}\left\{\mathbf{P}\left(\mathbf{w}_{s}^{o}\right) \boldsymbol{\Omega}\right\}-\boldsymbol{\epsilon}^{* \mathrm{~T}} \boldsymbol{\Omega}^{1 / 2} \mathbf{P}\left(\mathbf{w}_{s}^{o}\right) \boldsymbol{\Omega}^{1 / 2} \boldsymbol{\epsilon}^{*}\right]^{2 G} \delta^{-2 G} \xi_{n}^{-2 G}\right\} \\
\leq & C \delta^{-2 G} \xi_{n}^{-2 G} \sum_{s=1}^{S_{n}} \operatorname{trace}{ }^{G}\left\{\boldsymbol{\Omega}^{1 / 2} \mathbf{P}\left(\mathbf{w}_{s}^{o}\right) \boldsymbol{\Omega} \mathbf{P}\left(\mathbf{w}_{s}^{o}\right)^{\mathrm{T}} \boldsymbol{\Omega}^{1 / 2}\right\} \\
\leq & C \delta^{-2 G} \xi_{n}^{-2 G} \lambda_{\max }^{G}(\boldsymbol{\Omega}) \sum_{s=1}^{S_{n}} \operatorname{trace}^{G}\left\{\boldsymbol{\Omega}^{1 / 2} \mathbf{P}\left(\mathbf{w}_{s}^{o}\right) \mathbf{P}\left(\mathbf{w}_{s}^{o}\right)^{\mathrm{T}} \boldsymbol{\Omega}^{1 / 2}\right\} \\
\leq & C \delta^{-2 G} \xi_{n}^{-2 G} \lambda_{\max }^{G}(\boldsymbol{\Omega}) \sum_{s=1}^{S_{n}} R_{n}^{G}\left(\mathbf{w}_{s}^{o}\right), \tag{S.5}
\end{align*}
$$

where $C$ is a positive constant. Combining (S.5) and Condition 2, we can obtain (S.3).
Finally, we prove (S.4). For this purpose, we first note that Equation (2.3) implies that

$$
\begin{align*}
& L_{n}(\mathbf{w})-R_{n}(\mathbf{w}) \\
= & \|\mathbf{P}(\mathbf{w}) \mathbf{y}-\boldsymbol{\mu}\|^{2}-\|\mathbf{P}(\mathbf{w}) \boldsymbol{\mu}-\boldsymbol{\mu}\|^{2}-\operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega} \mathbf{P}^{\mathrm{T}}(\mathbf{w})\right\} \\
= & \|\mathbf{P}(\mathbf{w}) \boldsymbol{\epsilon}\|^{2}-\operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega} \mathbf{P}^{\mathrm{T}}(\mathbf{w})\right\}-2 \boldsymbol{\epsilon}^{\mathrm{T}} \mathbf{P}(\mathbf{w})^{\mathrm{T}} \mathbf{A}(\mathbf{w}) \boldsymbol{\mu} . \tag{S.6}
\end{align*}
$$

Hence, (S.4) holds if we can verify that

$$
\begin{equation*}
\sup _{\mathbf{w} \in \mathcal{W}}\left[\left|\boldsymbol{\epsilon}^{\mathrm{T}} \mathbf{P}(\mathbf{w})^{\mathrm{T}} \mathbf{A}(\mathbf{w}) \boldsymbol{\mu}\right| / R_{n}(\mathbf{w})\right]=o_{p}(1) \tag{S.7}
\end{equation*}
$$

and

$$
\begin{equation*}
\sup _{\mathbf{w} \in \mathcal{W}}\left[\| \| \mathbf{P}(\mathbf{w}) \boldsymbol{\epsilon} \|^{2}-\operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \boldsymbol{\Omega} \mathbf{P}^{\mathrm{T}}(\mathbf{w})\right\} \mid / R_{n}(\mathbf{w})\right]=o_{p}(1) . \tag{S.8}
\end{equation*}
$$

From (A.2), we know that for $\mathbf{w}^{*} \in \mathcal{W}$ and $\mathbf{w} \in \mathcal{W}$, we have that

$$
\begin{align*}
\left\|\mathbf{P}\left(\mathbf{w}^{*}\right)^{\mathrm{T}} \mathbf{A}(\mathbf{w}) \boldsymbol{\mu}\right\|^{2} & \leq \lambda_{\max }\left\{\mathbf{P}\left(\mathbf{w}^{*}\right) \mathbf{P}\left(\mathbf{w}^{*}\right)^{\mathrm{T}}\right\}\|\mathbf{A}(\mathbf{w}) \boldsymbol{\mu}\|^{2} \\
& \leq \lambda_{\max }^{2}\left\{\mathbf{P}\left(\mathbf{w}^{*}\right)\right\}\|\mathbf{A}(\mathbf{w}) \boldsymbol{\mu}\|^{2} \\
& =O(1)\|\mathbf{A}(\mathbf{w}) \boldsymbol{\mu}\|^{2}, \tag{S.9}
\end{align*}
$$

and

$$
\begin{align*}
\operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \mathbf{P}\left(\mathbf{w}^{*}\right)^{\mathrm{T}} \mathbf{P}\left(\mathbf{w}^{*}\right) \mathbf{P}^{\mathrm{T}}(\mathbf{w})\right\} & \leq \lambda_{\max }\left\{\mathbf{P}\left(\mathbf{w}^{*}\right)^{\mathrm{T}} \mathbf{P}\left(\mathbf{w}^{*}\right)\right\} \operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \mathbf{P}^{\mathrm{T}}(\mathbf{w})\right\} \\
& \leq \lambda_{\max }^{2}\left\{\mathbf{P}\left(\mathbf{w}^{*}\right)\right\} \operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \mathbf{P}^{\mathrm{T}}(\mathbf{w})\right\} \\
& =O(1) \operatorname{trace}\left\{\mathbf{P}(\mathbf{w}) \mathbf{P}^{\mathrm{T}}(\mathbf{w})\right\} . \tag{S.10}
\end{align*}
$$

Now with Condition 2, (2.3), (S.9), and (S.10) readily there, we can follow exactly the same steps as those in (A.4) and (A.5) of Wan et al. (2010) to obtain (S.7) and (S.8). This completes the proof.

## S. 3 Additional simulation studies

## S.3.1 Comparison with linear model averaging

To see how much harm it can cause by ignoring the nonlinearity, we first compare our method with linear model averaging (LMA) that considers all candidate models to be fully linear. Theoretically, LMA should work better if the model is linear or the degree of nonlinearity is small since nonparametric estimation converges much slower and is generally less efficient than least squares. As the degree of nonlinearity increases, better fit of nonparametric estimation dominates its efficiency loss and slow convergence, and thus MAPLM should outperform LMA. To confirm this theoretical argument, we make the comparison between MAPLM and LMA in three data generation processes with different nonlinear functions, i.e.

DGP1: $g_{1}\left(z_{i 1}, z_{i 2}\right)=2\left(z_{i 1}-0.5\right)^{3}+\sin \left(z_{i 2}\right)$,
DGP2: $g_{2}\left(z_{i 1}, z_{i 2}\right)=\exp \left(z_{i 1}\right)+z_{i 2}^{2}$,
DGP3: $g_{3}\left(z_{i 1}, z_{i 2}\right)=\exp \left(z_{i 1}\right) * z_{i 2}^{2}$.

The degree of nonlinearity of the three functions is shown in Figure S.1. Clearly, $g_{3}$ generates the most nonlinear relationship. $g_{2}$ is slightly more nonlinear than $g_{1}$, both of which are closer to linearity than $g_{3}$. Hence, we expect that the performance of MAPLM and LMA is comparable under $g_{1}$ and $g_{2}$, but MAPLM should demonstrate more superiority under $g_{3}$. Also, because of the above-mentioned tradeoff between better fit and efficiency, the relative performance of MAPLM and LMA depends on the signal-to-noise ratio, the sample size, and the degree of uncertainty in model specification. We shall examine the effect of these factors in turn.

Figure S.1: Nonlinear functions in three data generation processes

We first consider the case where there is uncertainty only in the linear component, and the results are given in Figures S.2. First, we see that MAPLM generally demonstrates its superiority over LMA when $R^{2}$ and sample size are moderate or large, except in DGP1 with small degree of nonlinearity. As the $R^{2}$ and sample size decrease, LMA performs better than MAPLM. This is not surprising because nonparametric estimation tends to fit the noise more than least squares when $R^{2}$ is small, and it suffers from the curse of dimensionality when the sample size is small. Next, we examine how the degree of nonlinearity influence the performance. As expected, the advantage of MAPLM becomes more prominent as the degree of nonlinearity increases. In particular, LMA slightly outperforms MAPLM in most of cases of DGP1 where nonlinearity is weak, but their discrepancy is small. As the degree of nonlinearity increases in DGP2, MAPLM outperforms LMA when $R^{2} \geq 0.5$. With a large sample size $n=400$, MAPLM beats LMA even when $R^{2}=0.3$. In DGP3 with the largest degree of nonlinearity, MAPLM outperforms LMA for a even wider range of $R^{2}$. It starts to dominate LMA under $R^{2}=0.3$ even when $n=200$, and the disadvantage of LMA under large $R^{2}$ is magnified.

We then consider the second case where there is uncertainty in both linear and nonlinear components (structure uncertainty), and the results are presented in Figures S.3. In this
case, MAPLM shows a dominant superiority over LMA over the whole range of $R^{2}$ in all DGPs and all sample sizes.

In general, we observe a tradeoff between better fit and efficiency in choosing between MAPLM and LMA. MAPLM containing a nonparametric component can better capture the nonlinear pattern, but converges slower and is less efficient than least squares. Therefore, when the degree of nonlinearity is large, better fit of nonparametric estimation dominates its efficiency loss and slow convergence, and this results in better performance of MAPLM than LMA. A large signal-to-noise ratio and a large sample size also favour MAPLM as both of these two situations help improve efficiency. Moreover, we find MAPLM more robust than LMA. Under weak nonlinearity when LMA works especially well, MAPLM is only slightly inferior to LMA. However, LMA can perform much worse than MAPLM and other methods in some situations.

## S.3.2 Simulation results of additional data generation processes

First, to examine whether the simulation results are affected by expanding model space, we consider additional experiment designs. In particular, in the first case with uncertainty only in the linear component, we let the number of candidate models increase from 7 $\left(=2^{3}-1\right)$ to $31\left(=2^{5}-1\right)$, and further to $127\left(=2^{7}-1\right)$ as the sample size increases from 50, 100, to 200 . In the second case with uncertainty both in the linear and nonlinear component, we let the number of candidate models vary from 12 to 50 , and further to 133 as the sample size increases. In both cases, we generate the nonlinear component using the function $g(z)=\exp (z)+z^{2}$. The results are presented in Figure S.4. We see that the results are highly robust. With diverging number of candidate models, the superiority of MAPLM over linear model averging is even more obvious, which suggests that MAPLM is particularly useful when the model space is large.

Second, to mimic possible serial correlation in the empirical data, we consider data generation process with autoregressive errors. In particular, we generate the error as $\epsilon_{i}=\sigma\left(0.75 \epsilon_{i-1}+u_{i}\right)$, where $u_{i}$ follows a normal distribution with zero mean and variance 0.75 , and $\sigma$ controls the signal-to-noise ratio. The results are provided in Figure S.5, and the relative performance of competitive methods is hardly affected.
